**SUMMARY**

(WCR), *Diabrotica virgifera virgifera*, - The Western corn rootworm (WCR), *Diabrotica virgifera virgifera*, is one of the most damaging insect pests of maize in North America and Europe. In Bulgaria the pest is distributed in almost all regions. Recently it was reported that KLP+ traps baited with dual semiochemical (pheromone and floral)

		(Csalomon®, , , )	lures (Csalomon®, Plant Protection Institute, HAS, Budapest, Hungary) showed very high efficiency at different population densities of the pest in this country. Increased knowledge about the optimal combination of visual and chemical cues of the trap would contribute to more effective management strategies of WCR. In 2017-2018, we compared yellow and fluorescent yellow KLP+ traps baited with dual lures in a maize crop in Knezha, north-western Bulgaria.
2017	2018	WCR -	-
		WCR - -	The hue of yellow colour tested did not elicit a strong behavioural response on WCR adults - no significant difference in captures between treatments was found during the study.
		2018 - -	The seasonal patterns of captures showed longer period of activity of WCR adults in 2018 - before the middle of July to the second half of September than the previous results obtained by attractant traps in Knezha (2014-2016) (from second half of July to the middle of September). Information on the relative abundance of fourteen other insect species captured in the traps is also presented.

## INTRODUCTION

Since the early nineties, when the first adults of the Western corn rootworm (WCR), *Diabrotica virgifera virgifera* LeConte, 1858 (Chrysomelidae) were registered near Belgrade, former Yugoslavia (Ba a, 1994), after several introduction events to different parts of Europe (Ciosi et al., 2008), the spread of the species permanently increased (EPPO, 2019). After the first record from Bulgaria (Ivanova, 2002), at the present time the pest is distributed in almost all

## RESULTS AND DISCUSSION

The yellow and fluorescent yellow KLP+ traps baited with dual lures, and placed at the same height showed no significant difference in the captures of WCR adults in 2017 and 2018, respectively (Table 1). In 2017, higher captures of WCR adults were recorded in yellow traps while in 2018, when the population density of the pest was relatively higher, the beetles were more numerous in fluorescent yellow trap. These results coincide with the results obtained by Tóth et al. (2003) and Toshova et al. (2017a) who reported that fluorescent yellow sticky traps captured higher mean number of beetles among the unbaited sticky traps of different colours, including yellow colour but without significant difference among the treatments. Similarly different hues of yellow colour do not influence the attraction of the adults of *Liriomyza huidobrensis* (Blanchard, 1926) (Diptera: Agromyzidae) (Durmu o lu et al., 2009).

Studying the effect of fluorescence on attractiveness of flower-visiting insects, Shrestha et al. (2019) reported that Coleoptera and Lepidoptera were captured significantly more frequently by pan traps displaying fluorescent properties (including fluorescent yellow traps) than by non-fluorescent pan traps.

Preference to fluorescent yellow colour has been reported for other coleopteran species: *Oxythyrea funesta* (Poda, 1761) (Vuts et al., 2008), *O. cinctella* (Schaum, 1841) (Coleoptera, Cetoniidae) (Vuts et al., 2012), *Plagionotus floralis* (Pallas, 1776) (Imrei et al., 2014), *Pseudovadonia livida* (Fabricius, 1776) (Toshova et al.

*Pseudovadonia livida* (Fabricius, 1776) (Toshova et al. 2016), *Brassicogethes aeneus* (Fabricius, 1775) (= *Meligethes aeneus* F., 1775) (Coleoptera, Nitidulidae) (Döring et al., 2012) and *Propylea quatuordecimpunctata* (Linnaeus, 1758) (Coccinellidae) (Toshova et al., 2017a). (Coccinellidae) (Toshova et al., 2017a).

The seasonal pattern of *D. v. virgifera* captures in 2017 and 2018 in the KLP+ baited traps, is shown in Fig. 1. In both years, the beginning of the flight of adults was missed because of the late installing of the traps. In 2017, captures were registered in the period of July 21 – August 30, and in 2018 - from July 15 to September 21. In 2017-2018, an earlier appearance (before the middle of July) of *D. v. virgifera* adults was registered than 2014-2016 (end of July) at the same locality, and the period of the activity was more than two weeks longer in 2018 in comparison with 2014 (Toshova et al., 2017a) and 2015-2016 (Toshova et al., 2017b).

**Fig. 1. Seasonal flight of *D. v. virgifera*, Knezha, 2017 and 2018.** Arrows (↓) show the dates of the beginning and the end of the test. Asterisk (\*) indicates the date when lures were replaced

In 2018, significant positive correlations were found between the captures *D. v. virgifera* and the following meteorological factors: T min ( $r_s = 0.53, P = 0.01$ ), T mean ( $r_s = 0.59, P = 0.003$ ), relative air humidity ( $r_s = 0.57, P = 0.005$ ) and precipitation ( $r_s = 0.52, P = 0.01$ ). The significant positive correlation between WCR captures and relative air humidity and precipitation can be explained by captures of the adults in dry periods of the day/ night on dates with intense random rainfalls. In Bulgaria, most short-lived and heavy rains fall during the summer months (June, July and August) (Malcheva, 2017). Investigations on the daily dynamics of activity of the adults by Tóth et al. (2010) showed pronounced period of responsiveness of WCR adults to the floral and pheromone lures in the field. Beetles responded to the floral lure only during the day time hours, with well-defined peaks in the late morning and late afternoon, while the responses to the synthetic pheromone lure were recorded apart from daytime hours also well into the night.

In 2017 and 2018, besides WCR adults and the numerous unidentified dipteran specimens, the following taxa were recorded in the traps:

Coleoptera: *Agriotes ustulatus* (Schaller, 1783) (Elateridae) (4 specimens, KLP+ yellow traps, 15-30.07.2018; 10 specimens, KLP+ fluorescent yellow traps, 15-24.07.2018), *Harmonia axyridis* Pallas, 1773 (Coccinellidae) (20 specimens, KLP+ yellow traps, 17.07.-21.09.2018; 33 specimens, KLP+ fluorescent yellow traps, 22.08.-21.09.2018), *Coccinella septempunctata* Linnaeus, 1758 (1 specimen, KLP+ yellow trap, 19-21.09.2018; 2 specimens, KLP+ fluorescent yellow trap, 10.08.-03.09.2018), *C. quinquepunctata* Linnaeus, 1758 (1 specimen, KLP+ yellow trap, 07-10.08.2018) and *P. quatuordecimpunctata*

### SUMMARY

During the period 2016-2017 in the experimental field of Experimental Station on Soybean - Pavlikeni, was conducted field experiment in order to determine the reaction of soybean (*Glycine max* (L.) Merr.) variety Ritchie to the approved herbicides for wide-range on soil application [Gardoprim plus Gold 500 SK (312,5 g/l S-metolachlor + 187.5 g/l terbutylzine), Stomp aqua (455 g/l pendimethalin), Spectrum (720 g/l dimethenamide-P) and Wing-P (250 g/l dimethenamide-P + 212.5 g/l pendimethalin)] applied at optimal and dual high doses in conditions of Central North Bulgaria.

It was found that: the two-component herbicide Gardoprim plus Gold 500 SK and Spectrum allow their use of dual high doses for weed control in a mixed type of weed infestation in soybeans variety Ritchie where in are formed practically

(	9.4%)		similar yields (the observed reduction in yield reaches 9.4%) compared to the control variant - no weeds throughout the growing season of the crop; The applied doses of Stomp aqua and Wing-P at standard doses (350 and 400 ml/da) did not produce a phytotoxic effect on soybean variety Ritchie. When applied in dual high doses, they produce a phytotoxic effect with easily recognizable symptoms of growth retardation and leaf deformity, which are partially overcome at a later stage of soybean development; Stomp aqua applied in dual high doses has a phytotoxic effect on the tested soybean variety Ritchie and reduces (from 4.2 to 32.3, average 18.1%) the yield of soybean grain during the years of study.

## INTRODUCTION

Weeds, diseases and pests are one of the main factors that reduce yields and impair soybean quality.

A characteristic biological feature of soybeans (*Glycine max (L.) Merr.*) is the slow rate of growth in the early stages of its development, making it highly vulnerable to the competitive impact of weeds (Hartzler, 2007; Rich and Renner, 2007; Keramati et al., 2008; Fickett et al., 2013). A number of studies have shown that the decrease in soybean grain yield depends on the degree and duration of weed infestation of crop and on the amount precipitation and distribution of growth stage from crop development (Alexieva and Stoimenova, 2004; Marinov-Serafimov, 2005; Chirila and Chirila, 2008; Nagaraju and Kumar, 2009).

Effective control of weed species in soybean crops had an important role in the technology of its cultivation, which is why herbicides (proven by their efficiency, easy applicability and quick initial action)

		) (Tzi-Bun, 2011; Peer et al., 2013).	occupy the largest share of used pesticides (Tzi-Bun, 2011; Peer et al., 2013).  The availability of a large number of herbicides on the market, as well as the lack of systematic studies on their effectiveness under specific agrometeorological conditions, depending on the species composition and degree of weed infestation of soybean crops, very often manufacturers are difficult to choose. On the other hand, the systematic introduction of herbicides into production areas is a prerequisite for a systemic stress factor that directly and indirectly affects plants (Hristova, 2009; Hristova et al., 2013; Peer et al., 2013; Goranovska et al., 2014; Georgiev, 2015; Goranovska et al., 2017; Pavlovski et al., 2017; Georgiev, 2020).
(L.) Merr.)	( <i>Glycine max</i> (L.) Merr.)	-	The aim of the study is to determine the response of soybeans ( <i>Glycine max</i> (L.) Merr.) variety Ritchie to approved broad-spectrum for soil application herbicides in optimal and dual high doses in Central Northern Bulgaria.
2016-2017	. .	-

## MATERIAL AND METHODS

The studies were carried out in the period 2016-2017 in the experimental field of Experimental Station on Soybean - Pavlikeni on medium-leached chernozem under non-irrigated conditions.

The experiment was set up using the block design method in four replications and the size of the experimental plot of 5 m<sup>2</sup> with soybean (*Glycine max* (L.) Merr.) variety Ritchie. It was studied herbicide selectivity Gardoprim plus gold 500 CK (312.5 g/l S-metolachlor + 187.5 g/l terbutylzine), Stomp aqua (455 g/l pendimethalin), Spectrum (720 g/l dimethenamide-P) and Wing-P (250 g/l dimethenamide-P + 212.5 g/l pendimethalin) applied at optimal and dual high dose, after sowing, before emergence of the crop (BBCH 00) (Hess et al., 1997) (Table 1).

## 1.

l/da.	„ptp 18“ – 30	The application of the all herbicides were conducted with 30 l/da water solutions using a spreading machine „ptp 18“ with. The following characteristics were assessed on 7, 14, 21, 30 and 45 day after emergence of crop. Phytotoxicity on herbicides, using the 1-9 scale of the EWRS (European Weed Research Society) (score 1 – no damage and score 9 – completely destroyed crop); crop vigour was determined according to a 11 score scale, where 0 - completely dead plants and 10 - very healthy growing plants (Shinggu et al., 2009) and seed yield, kg/da.
7, 14, 20, 30 45	-	In the test areas during the vegetation of the crop, in the variants for determining the selectivity of the herbicides, all available weeds were removed manually (King et al., 2001).
EWRS (European Weed Research Society) (1 – 9 – ) al., 2009)	- ( 0 - 10 ) , kg/da.	Meteorological indicators are taken into account - the sum of rainfall (in mm) and average monthly air temperature (in 0 °C) during the growing season of the soybean. To characterize the aridity during the vegetation period, the de Martonne index (Paltineanu et al., 2007) was used.
,	-	The mathematical and statistical processing of the experimental data was done with the software STATGRAPHICS Plus for Windows Version 2.1.

## RESULTS AND DISCUSSION

The analysis of the main meteorological indicators shows that the amount and distribution of rainfall during the growing season of soybean (IV-IX) during the survey years (2016-2017) are different from the same for the multiannual period (1961-2000) (Figure 1).

**Fig. 1. Monthly average air temperatures and monthly precipitation during the soybean growing season on 2016 and 2017 and the average period 1964-2000.**

+13.8	+30.8%
-7.3	-83.8%
1961-2000	
83.4 (2017)	

.) 97.6 mm (2016 .).

1 ,

2016

2017 .

(120.5 mm)  
105.9 mm

(106.0 mm),  
2016

Rainfall is characterized by high variability - increased from + 13.8 to + 30.8% and decreased from -7.3 to -83.8% compared to multi-year period 1961-2000 at precipitation amplitude of 83.4 (2017) to 97.6 mm (2016).

Figure 1 showed that during the study period, the least amount of rainfall was recorded in the months of July-August 2016, which has a detrimental effect on the growth and development of soybeans. Increased rainfall in 2017 in the early stages of soybean development is April (120.5 mm) and May (106.0 mm), as well as 105.9 mm in 2016 are prerequisites for causing a stronger phytotoxic effect herbicides containing the active ingredient pendimethalin.

$8.5^{\circ}$  (2017 .)       $0.3$  (2016 .)       $4.4^{\circ}$  (2017 .)  
 $12.4^{\circ}$  (2017 .)      .  
 $($   
 $),$   
 $: 2017 (I_{ar-DM} = 33.0$  )  
 $2016 (I_{ar-DM} = 18.1$  )  
 $($  1 2).

The monthly average air temperatures differ from the above normal values from  $0.3$  to  $4.4^{\circ}\text{C}$  and the amplitude from  $8.5^{\circ}\text{C}$  (2016) to  $12.4^{\circ}\text{C}$  (2017) compared to the values for the multiannual period.

Estimating the complex effect of some major meteorological factors (monthly rainfall and monthly average air temperatures), the study period can be conditionally classified into two groups: 2017 ( $I_{ar-DM} = 33.0$  humid) with relatively favourable conditions, whereas 2016 ( $I_{ar-DM} = 18.1$  semi arid) with unfavourable conditions as regards the biological requirements of soybeans (Figure 1 and 2).

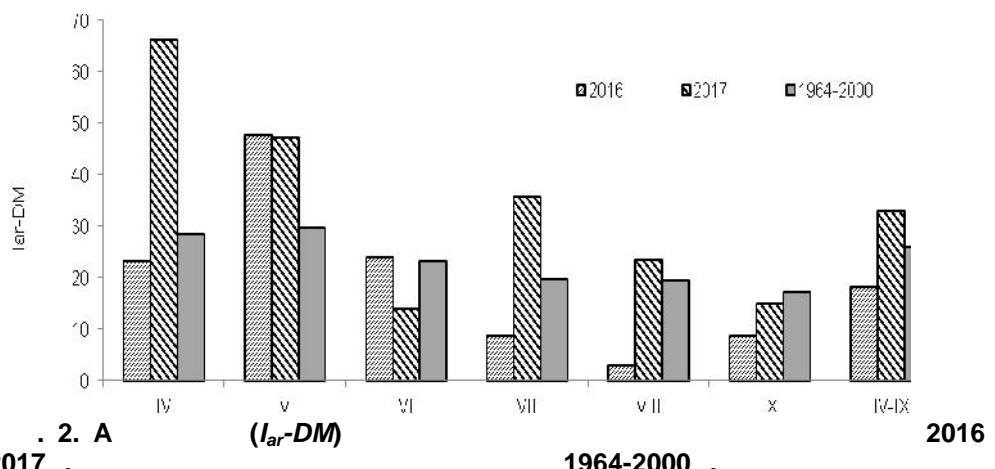

Fig. 2. Aaridity ( $I_{ar-DM}$ ) during the soybean growing season on 2016 and 2017 and the average period 1964-2000

EWRS ,  
 $500$  +  $187,5$  g/l  
 $(312,5$  g/l S- )  
 $($  1).  
 $($  2).

Visual readings on the scale of EWRS phytotoxicity scores indicate that Gardoprim plus Gold 500 CK herbicides (312.5 g/l S-metolachlor 187.5 g/l terbutilzine) and Spectrum (720 g/l dimethenamide-P) applied in optimal and dual high doses have very good selectivity (score 1) for the tested soybean variety Richie during the years of study (Table 2).

				The analysis of the data shows that with the application of Stomp aqua in dual high doses 7 (DAT) days after treatment in years well covered with rainfall (2017) during the sowing period (BBCH 00) and the initial stages and development of soybean (BBCH 11-13) produces a weak phytotoxic effect (score 2-3) on the crops.
( 2-3)				By extending the growing season - 21 to 45 (DAT) days after soybean treatment, a stronger phytotoxic effect (score 4.6-6.8) is manifested in easily recognizable symptoms of chlorosis and retardation in plant growth. In years with relatively less rainfall (2016) in the critical growth stage of soybean development, the observed symptoms are remain (score 2-3), which is later partially overcome.
(2016 .)				The newly emerged leaves are free from visible changes from the effects of the herbicide, which can be explained by the reduced amount of rainfall in the later stages of crop development.
				The two-component, broad-spectrum herbicide Wing-P (250 g/l dimethenamide-P + 212.5 g/l pendimethalin) applied in dual high doses caused a slight phytotoxic effect during the study period (score 2). Until the end of soybean vegetation, the differentiation between optimal and dual high applied doses herbicide is maintained. The results obtained in tracing the viability of the culture are similar (Table 2).
				The effect of the applied herbicides reported on soybean grain yield varies by years within relatively narrow limits (Figure 3).

Legend: GPG - Gardoprim plus gold 500 CK (312.5 g/l S-metolachlor + 187.5 g/l terbutylzine); SA - Stomp aqua (455 g/l pendimethalin); SP - Spectrum (720 g/l dimethenamide P); UP - Wing-P (250 g/l dimethenamide-P + 212.5 g/l pendimethalin); % Ct – relative yield, percentage of control variant; a, b, c - statistically significant differences at  $P = 0.05$ .

### 3.

**Fig. 3. Influence of the applied optimal and dual high doses herbicides on soybean yield**

145.8	200.4 kg/da,	(	-0.8
-18.1%	+0.1 12.6%)	-	-
		(	).

200.4 kg/da,  
kg/da (

145.8 176.6  
2.5 18.1%).

Average for the study period soybean grain yield ranges from 145.8 to 200.4 kg/da such as yield reductions in the range (from -0.8 to -18.1% and from +0.1 to 12.6%) compared to the control variant - untreated control (no weeds throughout the growing season).

The highest values for this indicator are reported in the variants treated with optimal doses of herbicides 176.6 to 200.4 kg/da, while in the case of applied dual high doses of herbicides, the reduction of yield is in the range 145.8 to 178.8 kg/da (the observed decrease in yield varies from 2.5 to 18.1%). The applied dual high doses of Stomp aqua and Wing-P induce a statistically significant inhibitory effect in the formation of soybean grain yield.

The experimental results obtained show that all applied herbicides at optimal doses do not influence the formation of soybean grain yield and are independent

			- of the amount and distribution of rainfall in the critical growth stages of crop development.
			- Despite the differences in values of this indicator by years, due to the differences in agrometeorological conditions, the trend between the different study variants remains. The reduction in soybean yield can be explained on the one hand by the amount and distribution of precipitation in the critical phases of crop development and on the other hand by the physical basis of the selectivity for the tested herbicides.
B			
	500 (312,5 g/l S- + 187,5 g/l (720 g/l - )		- The high selectivity of the two-component herbicide Gardoprim plus Gold 500 SK (312.5 g/l S-metolachlor + 187.5 g/l terbutylzine) and Spectrum (720 g/l dimethenamide-P) allow their use of dual high doses for weed control in a mixed type of weed infestation in soybeans ( <i>Glycine max</i> (L.) Merr.) variety Ritchie wherein are formed practically similar yields (established yield reduction up to 9.4%) compared to the control variant - no weeds throughout the growing season of the crop.

## CONCLUSIONS

The high selectivity of the two-component herbicide Gardoprim plus Gold 500 SK (312.5 g/l S-metolachlor + 187.5 g/l terbutylzine) and Spectrum (720 g/l dimethenamide-P) allow their use of dual high doses for weed control in a mixed type of weed infestation in soybeans (*Glycine max* (L.) Merr.) variety Ritchie wherein are formed practically similar yields (established yield reduction up to 9.4%) compared to the control variant - no weeds throughout the growing season of the crop.

The applied of Stomp aqua (455 g/l pendimethalin) and Wing-P (250 g/l dimethenamide-P + 212.5 g/l pendimethalin) at standard doses (350 and 400 ml/da) did not produce a phytotoxic effect on soybean variety Ritchie. When applied in dual high doses, they produce a phytotoxic effect with easily recognizable symptoms of growth retardation and leaf deformity, which are partially overcome at a later stage of soybean development.

Stomp aqua applied in dual high doses has a phytotoxic effect on the tested soybean variety Ritchie and reduces (from 4.2 to 32.3, average 18.1%) the yield of soybean grain during the years of study.

Schreb.)		( <i>Festuca arundinacea</i> Schreb.)		
		(Hannaway et al., 1999; Kir et al., 2010 Ge and Wang, 2015). 2010 .		Forage production, both at home and abroad, is one of the leading industries in modern agriculture (Capstaff and Miller, 2018). Global climate warming and increased livestock feed consumption necessitate the use of high yielding, stress-tolerant of abiotic factors perennial cereal feed grasses.
		,	-	
		-	-	
		-	-	
		-	-	
		-	-	
		-	-	
		( <i>Festuca arundinacea</i> Schreb.) -		Due to the high biological, ecological plasticity, tall fescue ( <i>Festuca arundinacea</i> Schreb.) had economically important in the production of fodder (hay and silage) for the agro-climatic conditions of central and Northern Europe. It is also used as a major component in the creation of artificial meadows and pastures, resistant to frequent mowing and grazing (Hannaway et al., 1999; Kir et al., 2010 and Ge and Wang, 2015). During 2010 in Institute of forage crops – Pleven was created the first for Bulgaria variety tall fescue ( <i>Festuca arundinacea</i> Schreb) - Albena.

The variety Albena is characterized by a very high persistence for more than

		ten years, winter hardiness, and tolerant of soil moisture.
		Weed control had an important role in technology of growing of tall fescue ( <i>Festuca arundinacea</i> Schreb.) (Dimitrova, 1984; Cole and Olstad, 2004; Harinder et al., 2006).
	( <i>Festuca arundinacea</i> Schreb.) (Dimitrova, 1984; Cole and Olstad, 2004; Harinder et al., 2006). Dimitrova (1984), Raeside et al. (2012) Jusoh (2013)	According to studies Dimitrova (1984), Raeside et al. (2012) and Jusoh (2013) a typical biological property of tall fescue, and other members of the group of perennial grasses, is slow growth and development during the year of stand establishment and highly sensitive to entanglement for weed infestant during seeds formation. In that periods, they are low competitiveness to weeds and very sensitive to weed infestans. During this period of development, tall fescue is highly sensitive to the competitive effects of weeds, which requires effective weed control. Therefore, the creation of well-compacted crops with good density is a prerequisite for the production of high-quality forage and seeds. All of this calls for systematic studies to identify herbicides on the market with high selectivity to tall fescue.
Young et al (1999), Mueller-Warrant and Rosato (2005), Dimitrova (1984).	( <i>Festuca arundinacea</i> Schreb.),	The selectivity of herbicides to tall fescue worldwide has been partially explored Young et al (1999), Mueller-Warrant and Rosato (2005), and are extremely limited in our country Dimitrova (1984).
2015-2017		The purpose of the study was to determine selective herbicides of tall fescue ( <i>Festuca arundinacea</i> Schreb.) to weeds control in the production of feed and seeds.

## MATERIAL AND METHODS

During the period of 2015-2017, a study was conducted in the experimental field of the Institute of Forage Crops - Pleven on a slightly leached chernozem soil under non-irrigating conditions. The experiment was set up using the perpendicular method and the size of the

5 m<sup>2</sup>

The herbicidal formulations used in this study at the indicated doses were registered for weed control in cereal-grain grown crops in Bulgaria with herbicide action against broadleaf weeds including those resistant to the herbicides: ccurate 60 WG (600 g/kg metsulfuron methyl), Ily Max (143 g/kg metsulfuron + 143 g/kg tribenuron methyl), and with complex action against annual and broadleaf weeds Eagle 75 WG (750 g/kg chlorsulfuron), including wild oat (*Avena fatua* L.) Axial One (45 g/l pinoxadene + 5 g/l florasulam), Basis 75 DF (250 g/kg thifensulfuron methyl + 500 g/kg rimsulfuron) and Pacifica WG (30 g/kg mesosulfuron-methyl + 10 g/kg odosulfuron-methyl sodium + 90 g/kg mefenpyr-diethyl) + Adjuvant Biopower in the cultivation of cereals.

The tall fescue (*Festuca arundinacea* Schreb.) Albena variety was sown in the early spring (March-April) at inter-row distance of 36 cm and sowing rate of 40-45 kg/ha. Stockpiling fertilizing was done with  $\frac{1}{2}$  5 - 100 kg/ha and N - 120 kg/ha ( $\frac{1}{2}$  in spring +  $\frac{1}{2}$  in autumn each year). The treatment was carried out in

2-4	(BBCH – 12-14)	-	growth stage 2-4 leaf (BBCH - 12-14) during year of sowing and the growth stage of the beginning of shooting up (BBCH – 21-34) (Hess et al., 1997)

## RESULTS AND DISCUSSION

The analysis of meteorological indicators shows that rainfall during the study period varies over a wide range - from 625.4 mm (2016) to 798.0 mm (2017). During the study period, rainfall was higher than 12.0 to 43.0% over the average for the multiannual period (1964-2014). The average annual temperature has a strong variability of + 0.9 to +1.8 °C

	+ 0.9	+1.8	<sup>0</sup> C	compared to the average values for the period 1961-2000.

Legend: EWRS – logarithmic scale (1 - 9) – score 1 – without damages, score 9 – the crop is completely destroyed,

<sup>1</sup> – during the establishing year of the stand, <sup>2</sup> – during seed production year, DAT – day after treatment

- Relatively high phytotoxicity in tall fescue has been reported following application of herbicides Axial One and Basis 75 DF. It is evident that with increasing dose on Axial One, the phytotoxic effect increases from 2 to 8 score, whereas treatment with Basis 75 DF with the highest dose studied causes a lethal effect (score 9), both in the year of sowing and in year of seed production.
- By increasing the vegetative period of the tall fescue 21, 30 and 45 days after treatment with Axial One and Basis 75 DF, the observed phytotoxic effect is maintained - peripheral chlorosis and anthocyanin staining at the base of the leaf, while the newly emerged leaves are without visible changes.
- Herbicides causing slight phytotoxic changes (score 2-3) in the tall fescue with increasing vegetation period observed symptoms are not preserved.

			-	Leaf staining recovers from but growth inhibition persists. After treatment with Pacifica WG – 175g/ha with the addition of Biopower adjuvant – 350 ml/ha) produces a strong phytotoxic effect (score 5-7) at the lowest applied dose (Pacifica WG – 350 or 535 g/ha with the addition of Biopower adjuvant – 700 or 1050 ml/ha) and at a higher lethal effect - score 9.

The selectivity of applied herbicides depending on the sensitivity of the tested variety of tall fescue is in a positive correlation depending on the dose of the applied herbicide ( $r$  ranged from 0.956 to 0.998) in negative dependence on crop vigour ( $r$  is within the limits -0.387 to -0.975) and ground cover ( $r$  is from -0.462 to -0.987) of the crop.

As a result of expressed phytotoxicity of the herbicides to complex action against annual and broadleaf weeds including wild oats (*Avena fatua* L.) Axial One, Basis 75 DF Pacifica WG + Biopower reduced the dynamics of accumulation of fresh (from 4.1 to 84.7%) and dry biomass (from 2.3 to 62.7%) in the year of the creation of the tall fescue, the differences being statistically significant compared to the control variant (Table 6).

### **SUMMARY**

Under laboratory conditions at the Institute of Forage Crops - Pleven was determined the effect of the growth stimulator Lactisem for pre-sowing treatment of seeds on germination and initial development in eight accessions of broomcorn (*Sorghum vulgare* var. *technicum* Körn.).

It was found that: Lactisem applied at dose of 3 l/100 kg of seeds had a stimulating effect on growth (cm) (from 5.5 to 47.4%) and weight gain (g) of seedlings (from 5.6 to 12.5%) in all accessions included in the study broomcorn; It has been demonstrated a specific variety reaction with regard to the effect of growth stimulator Lactisem on seedling growth and formation of fresh weight on seedlings in the tested accessions *Sorghum vulgare* var. *technicum* (Körn.). The strongest stimulatory effect of Lactisem on seedling growth was observed in local populations GL15A, S14, G16V and MI16N, and the weakest

<p>Szegedi 1023. The GL15A, G16V and MI16N local populations found superior and might be productive in further breeding programs.</p> <p><b>Key words:</b> pre-sowing treatment, seeds stimulating, <i>Sorghum vulgare</i> var. <i>technicum</i> [Körn.]</p> <h2>INTRODUCTION</h2> <p>Seed germination and initial development is vital to sustainable crop production. Good-quality seed has a significant potential of increasing productivity of crops. Efficient seed germination and early seedling establishment are important for they represent the most susceptible stages of the life cycle of crop plants (Hadas, 2004).</p> <p>Rapid and uniform seedling emergence leads to successful establishment as it produces a deep root system before the upper layers of soil dry out (Harris, 1996).</p> <p>Germination seeds can be improved using a variety of seed technologies. Improving seeds germination includes physical, physiological and biological treatments to overcome germination constraints, earlier crop development and better yields (Afzal, 2013).</p> <p>Germination and seedling establishment as an independent organism are critical phases in the life of a plant. Lactisim is a growth stimulant from the product range of Lactofol® of Ecofol AD intended for pre-sowing treatment of seeds. The product contains a balanced nutrient composition of macro- and microelements that are particularly important for the early development of young plants. The use of Lactisem increases germination energy and ensures good development of the root system even with poor agricultural technology. Lactisem improves the germination rate, guarantees a good start in the development of crops and reduces seed requirements for an area. Lactisem</p>
--	---

		is applicable to many cultivated plants.
	<i>Sorghum</i> (Ejeta and Knoll, 2007; Wagaw, 2019)	The <i>Sorghum</i> species are a multipurpose crop grown for food, animal feed and industrial purposes. According to studies of a number of authors (Ejeta and Knoll, 2007; Wagaw, 2019) <i>Sorghum</i> species are tolerant to many stresses, including heat, drought, salinity and flooding as compared to other cereal crops, but in early stages of development such conditions may delay development and reduce yields (Kebede et al., 2001; Calvino and Messing, 2012; O'Donnell et al., 2013). Sorghum plants with high vigour and fast growth rates during early developmental stages may be advantageous in regions affected by drought early in the growth season (Uptmoor et al., 2006). Variation in the reaction of stress in early growth stages among varieties of sorghum relative to should be utilized as a source for drought tolerant forms selection rather than relying on yield differences alone (Assefa et al., 2010).

Lidanski, 1988).			

#### Technique of bioassay

Hundred seeds from the tested genotypes broomcorn were germinated between layers of filter paper Filtrak 388 in 140 mm Petri dishes for each of the tested accessions broomcorn *Sorghum vulgare* var. *technicum* (Körn.). For each variant of the experiment, Lactisem was pipetted according to factor B. Samples were placed in a thermostat at 22 ± 2 °C for seven days in the dark. The following metrics are defined for all variants of the experiment.

**Effect assessment.** For assessing experimental results, the following parameters were used Biometric parameters: Number seeds germinated in each treatment; laboratory germination for each treatment (%); Length of shoot, root, and seedling, mm; Weight of fresh biomass of shoot, root, and seedling, g per plants.

The percentage of seed germination was calculated after preliminary arcsin - transformation following the formula,

$$y = \arcsin \sqrt{\left(\frac{X\%}{100}\right)}$$

forwarded by Hinkelmann and Kempthorne (1994). The statistical processing and significance of the difference between the investigated treatments was carried out with Statistica Software Package version 10 (StatSoft, Inc., 2011) by One-way ANOVA. Fisher's Least-Significant-Difference (LSD) test was used at the p<0.05 probability level.

The significant of influence of factors on a reliable factor variant is determined by  $\chi^2$  (Plohinsky, 1967 and Lidanski, 1988).

*Sorghum vulgare* var. *technicum* (Körn.).

– 3 l/100 kg (100%).

## RESULTS AND DISCUSSION

The effect of plant growth stimulant Lactisem on the germination of seeds and seedling growth of different accessions broomcorn *Sorghum vulgare* var. *technicum* (Körn.) was evaluated. The applied concentrations of growth stimulant Lactisem had a negligible effect under laboratory germination of seeds of accessions (Figure 1). Seed germination was highest on average for all accessions at the optimal dose of plant stimulator – 3 l/100 kg seeds (100%).

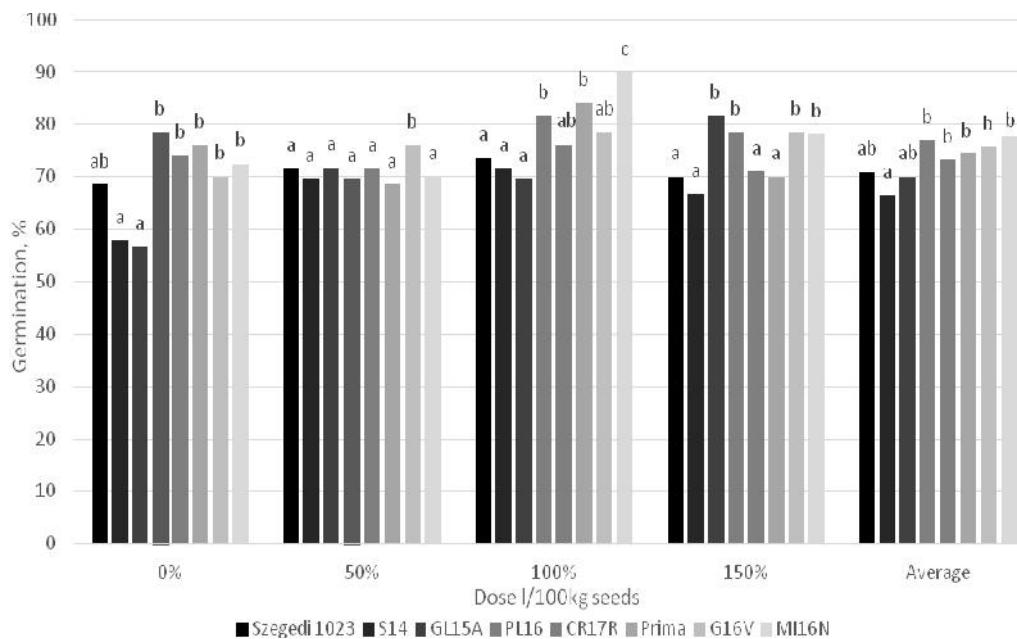

Fig. 1. Seed germination for the different doses of growth stimulator Lactisem applied in broomcorn accessions

( , , )  
, ,  
( $\chi^2=15.34$ ;  $\chi^2=13.71$ )  
( 1).

The analysis of variance to determine the effect of the studied factors (doses, accessions) and the interaction between them on laboratory germination showed that the influence of both factors (A, B) is approximately equivalent ( $\chi^2=15.34$ ;  $\chi^2=13.71$ ) to the total variation (Table 1). The complex influence of factors ( $\chi^2=31.04$ ) occupy a relatively

$^2=31.04$ )

big share of the total variation.

### 1.

- ( ) (cm) (1).
- (3 6 l/100 kg (2). (P=0.05) - - - 3 l/100 kg ( ) - - - 3 l/100 kg , , , 5.5 47.4%. - - - GL15A, S14, G16V MI16N.
- The doses of growth stimulant Lactisem applied to technical sorghum (broom) seeds had an effect on the length of the shoot and root (mm) (Table 1). There is an increase in shoot length at higher doses (3 6 l/100 kg seeds) of Lactisem for all tested accessions (Table 2). The length of the shoot average for the test accessions is proven (P=0.05) to be the greatest on at the optimal dose of 3 l/100 kg seeds Lactisem compared to the untreated control variants. Compared to the root in the broomcorn accessions has a longer length than the shoot. The differences in shoot length in the test accessions are unproven compared to the control variants in most of the specimens tested at the lowest dose tested. The shoot length averaged over the test accessions of broomcorn was greatest at a dose of 3 l/100 kg of seed, where it exceeded the control variant from 5.5 to 47.4%. Relatively strongest stimulation on sprout growth was reported in local populations GL15A, S14, G16V and MI16N.

*LSD* = 0.05

Legend: Different letters in columns indicate significant differences by the LSD test at  $p=0.05$  probability

In regard to the weight of the seedling, the differences between the tested accessions are insignificant (Table 1). The minimum value for the shoot weight was observed at dose 1.5 l/100 kg seeds average for tested accessions. At high doses (3 and 6 l/100 kg seeds) Lactisem values for root weight are the highest, but the differences were not statistically significant compared to control variants.

At the dose of 3 l/100 kg of seeds Lactisem the shoot weight on average for the test broomcorn accessions is greatest, where it exceed the control variant from 5.7 to 44.4%. The strongest stimulation on primary seedling weight was reported in local populations GL15A, G16V and MI16N the differences being statistically significant at  $P=0.05$ .

A number similar results were reported of studies at species of genus *Sorghum* describe an increase the root length, shoot length and total weight of their seedlings (Nguyen et al., 2019; Trevisan et al., 2018; Widawati and Suliasih, 2018).

Analysis of variance shows that the largest share of the total variation on the primary shoot and root length indicator is due to the joint effect of the two factors (A, B) ( $\Sigma^2 = 14.60$ ), with no statistically significant differences (Table 4). The effect of doses of the growth stimulant Lactisem (Factor A) had a relatively larger share of the total variation ( $\Sigma^2 = 11.74$ ) compared to Factor A (accessions) - ( $\Sigma^2 = 0.71$ ).

With regard to the distribution of variation among the factors that determine the fresh biomass accumulation (g per plant), show that the weight of Factor A (doses)  $\Sigma^2$  is 27.44. With a relatively small proportion of the total variation, the share of Factor B (accessions) -  $\Sigma^2$  is 6.40, with differences statistically proven at P=0.001. The variance due to the relationship "accessions-doses" is  $\Sigma^2 = 35.28$ .

1.5, 3 6 l/100 kg

The present study reveals opportunities to stimulation the development of shoot, root that promote faster rooting and development of plants after treatment with Lactisem. The effect of the growth stimulant Lactisem, applied at a dose of 3 l/100 kg of seeds, has a positive effect on the germination and growth of the shoot and root of the included in the study in different accessions of broomcorn.

There was a specific reaction with regard to germination and development at the primary seedling at local broomcorn populations GL15A, G16V and MI16N.

The experimental results obtained can be explained by genotypic differences, since comparisons between them were made under controlled conditions.

## CONCLUSIONS

The effect of eight accessions of broomcorn on the effect of different doses of growth stimulator Lactisem applied at doses of 1.5, 3 and 6 l/100 kg seeds under laboratory conditions was evaluated.

3 l/100 kg ( ) ( m) var. <i>technicum</i> (Körn.). MI16N	- , - - - , -	The growth stimulator Lactisem applied at dose of 3 l/100 kg of seeds promotes sprouting of shoot and root and increasing the weight of shoot and root, compared to the control variants in all accessions included in the study.  There was a specific variety reaction with regard to the effect of growth stimulator Lactisem on seedling growth (cm) and formation of fresh weight on seedlings (g) in the tested accessions <i>Sorghum vulgare</i> var. <i>technicum</i> (Körn.).  The local populations GL15A, G16V and MI16N found superior and might be productive in further breeding program. Selection can be made on the basis of these characters at early growth stage. It would be cost effective, less time consuming and less laborious to screen the germplasm at early stage.

**SUMMARY**

The influence of the temperature range 10, 15, 20, 25 and 30 °C on the germination of seeds and the growth of seedlings in Bulgarian local populations and introduced varieties of broomcorn (*Sorghum vulgare* var. *technicum* Körn.) of different origin was determined under laboratory conditions at the Institute of Forage Crops, Pleven.

Specific genotypic differences in seed germination and initial development of broomcorn accessions were determined depending on the influence of temperatures - 10, 15, 20, 25 and 30 °C. The highest germination was recorded in local populations GL15A (24.2 to 90.0%) and MI16N (56.7 to 90.0%), and the highest seedling length at MI16N (3.08 to 20.65, mean 11.21 cm) and variety Prima (1.32 to 16.89, average 12.35 cm).

range 10 ÷ 30 °C on the growth of shoots in broomcorn (*Sorghum vulgare* var. *technicum* Körn.) accessions, through allometry coefficients (CA), has been demonstrated. At temperature 20 °C, shoot and root growth is relatively proportional to all accessions, with the lowest values (0.29 to 0.78) of coefficient of allometry (CA).

Temperatures 10-15 °C retain the growth of the shoot compared to the root, which determines the relatively high CA values (from 4.00 to 2.85). The development of the shoot at temperatures of 25-30 °C is less inhibited (CA from 1.41 to 1.22).

Seeds from local populations GL15A and MI16N of broomcorn have been found to germinate and develop over a wide temperature range of 10 ÷ 30 °C and are of interest in the generation of temperature tolerant accessions, as well as in the application of herbicides in relatively adverse weather conditions and edaphic conditions.

**Key words:** temperature stress, broomcorn, selectivity, vigour index

## INTRODUCTION

Agriculture is among the most vulnerable sectors of the effects of climate change, as changes in temperature and rainfall have negative effects on the yield and quality of production.

The increase in the world's population in the coming years necessitates the urgent task of increasing agricultural production, necessitating the inclusion of alternative crops to address the emerging shortfall in the production of food, feed, raw materials for industry, biofuels and others (Gornall et al., 2010; Kikindonov and Slanev, 2011; Donchev and Kikindonov, 2015).

Due to its productive potential,

			widespread use for human food, animal feed/forage, ethanol production and other industrial products, ecological plasticity and tolerance to unfavorable abiotic factors, determine the species of the genus <i>Sorghum</i> (to which belongs <i>Sorghum vulgare</i> var. <i>technicum</i> [Körn.]) a perspective culture for inclusion in rotation, in global warming and drought conditions (Berenji and Dahlberg, 2004; Angelova et al., 2011; Stefaniak et al., 2012).
(Berenji and Dahlberg, 2004; Boutraa et al., 2010; Angelova et al., 2011; Stefaniak et al., 2012).	Bray et al. (2000), Razmi et al. (2013) Queiroz et al. (2018)		Bray et al. (2000), Razmi et al., (2013) and Queiroz et al. (2018) found that germination seeds in the species of the genus <i>Sorghum</i> is conditioned by many factors: seed species and size, permeability of seed coat, oxygen absorption of the seeds etc.
<i>Sorghum</i> (Pirasteh-Anosheh et al., 2011; Hamidi and Pirasteh-Anosheh, 2013).			The abiotic stress during at planting time can cause irreversible loss in yield potential in <i>Sorghum</i> species (Pirasteh-Anosheh et al., 2011; Hamidi and Pirasteh-Anosheh, 2013).
Pirasteh-Anosheh et al. (2011), Hamidi Pirasteh-Anosheh (2013).			It has been found that sowing at relatively lower and/or higher soil temperatures reduces the percentage of sprouted plants and inhibits the rate of growth of <i>Sorghum</i> species in the initial stages of plant development Pirasteh-Anosheh et al. (2011), Hamidi Pirasteh-Anosheh (2013).
(1985)	Singh		Earlier sowing in cold and humid soils results in rotting of the seeds, nevertheless Singh (1985) identifies sorghum "tolerant to cold" genotypes that germinate, develop overgrowth and give satisfactory grain yields under relatively cold conditions (but above freezing) air and soil temperature, while later sowing impedes friendly sprouting due to insufficient soil moisture in the sowing area (Yo et al., 2004).
			(Yo et al., 2004).

*Sorghum*

(Bibi and Ali, 2012; Donchev and Kikindonov, 2015; Queiroz et al., 2018).

( ) (*Sorghum vulgare* var. *technicum* Körn.)

( ) (*Sorghum vulgare* var. *technicum* Körn.)

2017-2019 ( 1).

The increasing trend in recent years of global warming and drought has led to the need to evaluate and select breeding of *Sorghum* species accessions with tolerance to water and temperature stress in the initial stages of their development (Bibi and Ali, 2012; Donchev and Kikindonov, 2015; Queiroz et al., 2018).

The objective of this study was to determine the effect of temperature on seed germination and seedling development of accessions of broomcorn (*Sorghum vulgare* var. *technicum* Körn.) under laboratory conditions.

## MATERIAL AND METHODS

The study was conducted under laboratory conditions at the Institute of Forage Crops - Pleven. The subject of the study are seeds of broomcorn accessions (*Sorghum vulgare* var. *technicum* Körn.) harvested from field trials for evaluation of local and introduced varieties by complex of morphological, biological, biochemical and economic qualities in the period 2017-2019 (Table 1).

STATGRAPHICS Plus for Windows Version 2.1 Statistica 10.

$t ^0\text{C}$  - 10, 15, 20, 25  $^0\text{C}$ ; G - germinated seeds, %.

The percentage of seed germination was calculated after preliminary *arcsin*-transformation following the formula, Y=arcsin ( $\% / 100$ ), forwarded by Hinkelman & Kempthorne (1994). The collected data were analyzed using the software STATGRAPHICS Plus for Windows Ver. 2.1 and Statistica Ver. 10. Due to the continuing trend and the uniformity of the experimental results obtained during the study period, the data are presented on average for the period.

## RESULTS AND DISCUSSION

The temperature range 10/15  $^0\text{C}$  is the limit when sowing broomcorn for the conditions of Central North Bulgaria.

The laboratory germination of seeds in the tested broomcorn accessions varies over a wide range – from 24.2 to 90.0% and depends on the biological characteristics of the crop and the temperature (Tables 1 and 2). The highest percentage of germinated seeds was reported in the temperature range 20-25  $^0\text{C}$ , and with a decrease of 10-15  $^0\text{C}$  or with an increase of 30  $^0\text{C}$  the percentage of germinated seeds decreased from 14.3 to 27.1%.

With an increase in temperature of 20-30 °C, the percentage of germinated seeds increased (from 12.9 to 50.0%) in local populations S14, GL15A, PL16 and MI16N, while at CR16LR and G16V the temperature of 30 °C had an indifferent effect on the studied indicator. An exception to the described dependence is found in the variety Szegedi 1023, in which the applied lower temperatures (15-20 °C) have no effect on laboratory germination of seeds and the temperature range 25 °C inhibits IR from 14.3 to 27.1% of their germination.

With respect to laboratory seed germination, local populations GL15A and MI16N can be conditionally determined to be indifferent to the temperature range

					tested, due to statistically unproven differences in study temperatures 20 °C.

10-15 °C,

As a result of the direct effect of the temperature range on the sprouting of seedlings in broomcorn accessions, coefficient of allometry (CA) varied from 0.29 to 4.65 (Table 4).

Higher values of coefficient of allometry (CA) (from 3.34 to 4.65 and from 0.99 to 3.60 respectively) are found at lower applied temperatures of 10-15 °C, and with their increase (20-30 °C), coefficient

(	0.74	11.87	)	(20-30 °C), ( )	-	of allometry (CA) decrease (from 0.74 to 11.87 times) in disproportionate temperature rise. At temperature of 20 °C, relative proportional development of shoot and root was reported for all accessions, and allometry coefficients (CA) had the lowest values (0.29 to 0.78).
0.29	,	0.78).	-	(25-30 °C)	-	The highest temperatures studied (25-30 °C) suppressed the relatively lower shoot development relative to the root in all the samples tested ( $CA_{average}$ 1.41 and 1.22, respectively).
(				1.41 1.22).	-	Significant genotypic differences were found between the test accessions, which can be conditionally grouped according to coefficient of allometry ( $CA_{average}$ ) in the following ascending order: MI 16N - 1.42 > Prima - 1.46 > Szegedi 1023 - 1.55 > G16V - 1.59 > CR16LR > 1.63 > PL16 - 1.67 > S14 1.70 > GL15A - 2.14.

: CA – coefficient of allometry; SVI – plants vigour index

Legend: CA – coefficient of allometry; SVI – plants vigour index

(SVI)	The plants vigour (SVI) viability depends on the same factors and follows the observed laboratory germination and germination dynamics of the tested broomcorn accessions (Table 4).
( ) ( 4). SVI,	Depending on the SVI averages, they can be conditionally grouped in the following

: G16V 5.27 > CR16LR - 6.28 > Szegedi 1023 – 6.36 > S14 6.55 > PL16 – 7.08 > GL15A – 7.32 > Prima – 7.53 > MI 16N – 8.37.

ascending order: G16V 5.27 > CR16LR - 6.28 > Szegedi 1023 - 6.36 > S14 6.55> PL16 - 7.08 > GL15A - 7.32 > Prima - 7.53 > MI 16N - 8.37.

, , , .), , .

The obtained results can be explained with genetic differences among genotypes, as the comparisons were made under the same conditions. However, under other conditions (other genotypes, duration of storage of grain, etc.), it can be expected that the results will be different, since germination is determined by a complex of multiple factors.

## CONCLUSIONS

- seed germination and initial development of broomcorn (*Sorghum vulgare* var. *technicum* Körn.) accessions were determined depending on the influence of temperatures - 10, 15, 20, 25 and 30 °C.  
 - The highest germination was recorded in local populations GL15A (24.2 to 90.0%) and MI16N (56.7 to 90.0%), and the highest seedling length at MI16N (3.08 to 20.65, mean 11.21 cm) and variety Prima (1.32 to 16.89, average 12.35 cm).  
 - The influence of the temperature range 10 ÷ 30 °C on the growth of shoots in broomcorn accessions, through allometry coefficients (CA), was found.  
 - At temperature 20 °C, shoot and root growth is relatively proportional to all accessions, with the lowest values (0.29 to 0.78) of coefficient of allometry.  
 - Temperatures 10-15 °C retain the growth of the shoot compared to the root, which determines the relatively high CA values (from 4.00 to 2.85). The development of the shoot at temperatures of 25 ÷ 30 °C is less inhibited (CA from 1.41 to 1.22).  
 - The local populations GL15A and MI16N of broomcorn have been identified to germinate and develop over a wide

- specific genotypic differences in seed germination and initial development of broomcorn (*Sorghum vulgare* var. *technicum* Körn.) accessions were determined depending on the influence of temperatures - 10, 15, 20, 25 and 30 °C. The highest germination was recorded in local populations GL15A (24.2 to 90.0%) and MI16N (56.7 to 90.0%), and the highest seedling length at MI16N (3.08 to 20.65, mean 11.21 cm) and variety Prima (1.32 to 16.89, average 12.35 cm).

The influence of the temperature range 10 ÷ 30 °C on the growth of shoots in broomcorn accessions, through allometry coefficients (CA), was found.

At temperature 20 °C, shoot and root growth is relatively proportional to all accessions, with the lowest values (0.29 to 0.78) of coefficient of allometry.

Temperatures 10-15 °C retain the growth of the shoot compared to the root, which determines the relatively high CA values (from 4.00 to 2.85). The development of the shoot at temperatures of 25 ÷ 30 °C is less inhibited (CA from 1.41 to 1.22).

The local populations GL15A and MI16N of broomcorn have been identified to germinate and develop over a wide

$0^{\circ}$ , $,$ , $,$ , $.$	$10 \div 30$ $,$ , $,$ , $.$	<p>temperature range of <math>10 \div 30^{\circ}\text{C}</math> and are of interest in the generation of temperature tolerant accessions, as well as in the application of herbicides in relatively adverse weather conditions and edaphic conditions.</p>
